

Project Abstract

The **Organ Donation Registry UI** is a simple frontend-based healthcare web application developed using **React.js**. The main purpose of this project is to create awareness about organ donation and provide an easy platform for managing donor and recipient information.

In this application, users can register as organ donors or recipients by entering details such as name, blood group, and organ type. The data is stored in the browser using **LocalStorage**, so no backend or database is required. The system also includes a basic matching feature that finds compatible donors and recipients based on blood group and organ type.

The project is designed with a user-friendly interface to make the process simple and easy to understand. It demonstrates how healthcare-related applications can be built using only frontend technologies like **HTML, CSS, JavaScript, React.js, and React Router**.

This project helps in understanding React concepts, component-based design, form handling, routing, and local storage management while promoting the social cause of organ donation.
